Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European patent convention).

---

**Description**

The basic elements of a simple elevator system are: a sheave, a counterweight, an elevator car, a compensating cable or counterweight rope, a hoist rope and a travelling cable. All of these are assembled in an elevator well or shaft in a well known manner. As a general rule, the elevator car is connected to a counterweight by a hoist rope threaded over one or more sheaves or pulleys located in the upper reaches of the shaft. One end of the compensating cable is connected to the counterweight and the other end to the bottom of the car in some cases after having been threaded over a compensating sheave located in the bottom of the elevator well. In most cases, however, the compensating cable is left to hang free without being threaded over a sheave. One end of the travelling cable is connected to the car bottom and the other into a junction box affixed to the elevator well sidewall. Signals are sent via the travelling cable to a means causing the car to obey commands sent thereover. The counterweight is essentially the same weight as the car and the weight of the hoist ropes essentially equal the weight of the compensating cable as more fully disclosed hereafter.

A prime function of the compensating cable is to provide dynamic weight counterbalance to the weight of the hoist rope(s) as the car goes up and down in the elevator shaft so that the car is dynamically balanced. For optimum performance, the aggregate weight of the hoist rope and travelling cable should be essentially equal to the weight of the compensating cable at any given position of the car in the elevator shaft. In addition, the length of the hoist rope between the car and sheave should be equal to the length of the compensating cable between the counterweight and the lowest portion of the compensating cable or, stated alternatively, the length of the hoist rope from car to counterweight is essentially equal to the length of the compensating cable from car to counterweight.

Prior art compensating cables usually were nothing more than a link chain. Constant raising and lowering of the elevator car caused such chain also to be raised and lowered, rubbing one link against the other causing noise and abrasion. Link chains when hung free in an elevator shaft (no bottom sheave) have tendency to form a "point" and not a loop, i.e., the side legs of the chain tend to converge on a single link and form a point at the terminus of the "loop" formed by the chain. Such a configuration results in a propensity of one leg of the chain to rub against another during car movement: noise and abrasion result. More often than not, chain type compensating cable would bang into the sidewalls of the elevator shaft and cause damage and additional noise. Noise was so much of a problem that some prior art compensating chain type cables either used a sash cord (a rope woven in the links of the chain) or employed a

5 plastic coating over the link chain. One such commercially available compensating chain sold under the trademark Quietlink and advertised to reduce noise and the need for a sash cord, is a link chain disposed in a plastic sheath, the plastic sheath being drawn down as close as possible to the individual link members. See, for example U.S. Patent No. 3,574,996.

10 DE—C—366479 describes a compensating cable for elevators with a high weight to volume/diameter achieved by the use of a lead supplement. Further, FR—A—1,229,203 shows a cable (not a compensating cable) comprising a core having a sheath filled with metallic particles.

15 The present invention does not just reduce noise and abrasion, it virtually eliminates them as well as the need for a sash cord. Compared to known prior art chain type compensating cable, the disclosed compensating cable has a higher weight per linear length, is smaller for a given weight per linear length, and has less lateral cable sway, i.e. it is less likely to bang into the sidewalls of the elevator shaft.

20 According to the present invention, a compensating cable for an elevator or the like comprises an elongated stress or load supporting member disposed in an elongated sheath, the volume of the sheath not otherwise occupied by the stress or load member being substantially occupied by a mixture of metal particles and plastics material.

25 When, compared to prior art link chain type compensating cables, a compensating cable in accordance with the present invention is far stiffer, inherently forms a free hanging loop between the car and counterweight whose legs are spaced apart, is noiseless and has an ease of travel unknown to the prior art.

30 In an embodiment of the present invention, the cable is flat with a plurality of spaced apart stress or load members each with their longitudinal axis arranged in a line and substantially coplanar with one another and the sheath is a jacket of flexible material containing a plurality of elongated spaced apart cavities therein, the longitudinal axes of the cavities being arranged in a line and substantially coplanar with one another; each cavity containing at least one stress or load member and the volume of the cavities, not otherwise occupied by the stress or load member or members, is substantially occupied by the metal and plastics mixture.

35 The above and other features of the present invention are illustrated, by way of example, in the drawings, wherein:

40 Figure 1 is a schematic representation of an elevator system employing a compensating member;

45 Figure 2 is a cross section of one embodiment of the compensating member of Figure 1 along line 2—2;

50 Figure 3 is a cross-section of some of the metal particles of Figures 2 and 4;

55 Figure 4 is a cross section of another embodiment of the compensating member of Figure 1 along line 2—2;

Figure 5 is a cross section of still another embodiment of the compensating member of Figure 1 along line 2—2;

Figure 6 is a cross section of an additional embodiment of the compensating member of Figure 1 along line 2—2;

Figure 7 is a cross section of another embodiment of the compensating member of Figure 1 along line 2—2; and,

Figure 8 is a cross section of an additional embodiment of the compensating member of Figure 1 along line 2—2.

As shown in Figure 1, the compensating cable 2 is connected to the bottom of car 8 and to the bottom of counterweight 4. Sometimes, but not always, the compensating cable may be traversed over compensating sheave 6 or it may hang free in a loop like control cable 10. (See element 15 in dotted line). As a general rule, the length of compensating chain 2 (from car 8 to counterweight 4) should be essentially the same length as hoist rope 1, i.e., from car 8 over sheaves 3 to counterweight 4 (excluding wrap around portion around the sheave(s) if any). Hoist rope 1 is connected to the roof of car 8, traversed over sheave 3 and connected to the top of counterweight 4. Because of safety factor reasons, there may be five or more hoist ropes and the aggregate weight of such hoist ropes should approximately equal the weight of compensating cable 2. This does not mean that if five hoist ropes are required, there must be five compensating cables. There may be only one compensating cable and a plurality of hoist ropes, so long as the length of compensating cable 2 (from car 8 to counterweight 4) is essentially the same as the length, but not the aggregate length, covered by all hoist ropes between car 8 and counterweight 4 and its weight is essentially equal to the aggregate weight of hoist ropes 1 and control cable 10. The weight of control cable 10 is usually negligible comparative to that of the hoist ropes, it is terminated at junction box 7, and car 8, and is used to govern the car movement in a manner well known to the art.

Turning to Figure 2, shown is a cross section of one embodiment of compensating cable 2. Plastic sheath 11 made from either a polyamide, a polyolefin, polyvinyl chloride, rubber, polyurethane or mixtures thereof, is primarily a tube in which there is disposed link chain 9, composed of a plurality of links interconnected one to another. See U.S. Patent No. 3,574,996 for an example. The volume delimited by the innermost surface of sheath 11 not otherwise occupied by link chain 9 (hereinafter referred to as "the volume") is essentially occupied by metal particles 13 suspended in plastic 12. The metal particles can be ferrous and nonferrous of any desirable particle size and shape, preferably between 0.50 and 1.0 mm in diameter in an amount so that 50 to 75 per cent of the volume is occupied by them. The balance of the volume is occupied by plastic 12, which may be of the same materials as listed above for sheath 11.

It will be noted that the outer surface of sheath 11 is not necessarily undulating, as taught by the prior art, and may present an essentially circular cross section as shown in Figure 2, although it may be undulating if desired. Metal particles 13 result in a compensating cable having a greater weight per linear length than prior art chains. When prior art compensating chains are compared to compensating cable of the instant invention, it has been found that for a given equal length, a prior art compensating chain having links made of 9.525 mm diameter steel was equivalent to a compensating cable of the instant invention having a chain made of steel links of only 6.35 mm in diameter. Link chains made from high tensile strength non-metallic materials such as nylons and aramids are also suitable. The link chain 9 or wire rope 14 may be made of steel, iron, polyamides, aramids or graphite as appropriate. The links of the chain of the invention have a propensity to stay fully extended because of filler material 12 and 13, contrary to prior art compensating chains that permitted the link chain to shrink in length as a result of one link sliding within the link to which it is connected. A fully extended link chain results in an evenly distributed weight, eliminates noise, abrasion of one link on another, preserves the cylindrical surface of sheath 11 and avoids the problem of sheath cracking, which is experienced when using chains of the type disclosed in U.S. Patent No. 3,574,996.

The method of making the compensating chain 2 involves apparatus and method steps known to the prior art. For example, U.S. Patent No. 3,574,996 teaches the method and apparatus of extruding a sheath over a preform (a link chain). A preform composed of link chain 9 and metal plastic volume 12 and 13 is first formed by means of extrusion. Thereafter plastic sheath 11 is extruded over the previously described preform.

Metals such as lead, iron, steel, copper and mixtures thereof have been found suitable for use in this invention having a preferred particle size so that all such particles will pass an opening of 1.00 mm, 10% maximum will not pass a screen opening of 0.84 mm, 85% minimum will not pass a screen opening of 0.60 mm and 97% minimum will not pass a screen opening of 0.50 mm. Some or all of such metal particles may be spherical and/or shapes other than spherical.

In Figure 4 there is shown another embodiment of the invention using a stranded metal wire rope 14 instead of a link chain 9. Most any commercially available wire rope has been found to be suitable, especially those made from twisted or stranded filaments of steel. Wire rope made from high tensile strength nylons and aramids are also suitable. Figures 5 and 6 disclose two additional embodiments of the invention employing a plurality of wire ropes (Figure 5) or link chains (Figure 6). Obviously there may be more than two link chains or wire ropes (see Figure 7) within a given sheath 11 and wire ropes may be substituted for link chains and treated as equivalents for purposes of this disclosure.

Shown in Figure 8 is a flat type embodiment of the compensating cable 2. It is composed of a plurality of spaced apart chains 9 and/or wires 14, each with their respective axis arranged in a line and in substantially coplanar relationship with one another. Sheath 11 is made from a flexible material, examples of which have been previously discussed and contains a plurality of elongated cavities 17, the longitudinal axes of which are also arranged in a line and in substantially coplanar relationship with one another. Each of the cavities contains at least one strength member (9 and/or 14); they may alternatively contain two or more chains or wires, like those shown in Figures 5, 6 and 7. The volume in the cavities not otherwise occupied by the chains 9 and/or wires 14 is substantially filled with metal particles 13 and plastic 12 as previously described. Element numbers common to Figures 2, 3, 4, 5, 6, 7 and 8 represent like elements first described.

As mentioned earlier, most elevator systems do not employ a bottom sheave 6, especially when the system is installed in a well or shaft 16. Systems installed in non-shaft or well situations where the compensating cable if left to hang free would be subject to wind or other forces usually employ sheave 6 or its equivalent. Chain type compensating members of the prior art if installed in a shaft or well 16 have a tendency to come together at a link point in the general location where loop 15 is shown. This arises out of the relatively limber nature of the chain and the restricted lateral space in the elevator shaft 16. The closer together the legs of compensating member 2 are to one another, the more likely a prior art compensating chain type member would exhibit this "point" tendency. It is at this point, which is a dynamic one as car 8 moves up and down, where one link strikes another, giving rise to undesirable noise and abrasion and a tendency of one leg of the chain to slam into the car.

#### Claims

1. A compensating cable (2) for an elevator or the like comprising an elongated stress or load supporting member (9, 14) disposed in an elongated sheath (11), characterised in that the volume of the sheath (11) not otherwise occupied by the stress or load member (9, 14) is substantially occupied by a mixture of metal particles (13) and plastics material (12).

2. A cable as claimed in claim 1 and further characterised in that the cable (2) is flat with a plurality of spaced apart stress or load members (9, 14) each with their longitudinal axis arranged in a line and substantially coplanar with one another and the sheath is a jacket (11) of flexible material containing a plurality of elongated spaced apart cavities (17) therein, the longitudinal axis of the cavities being arranged in a line and substantially coplanar with one another; each cavity containing at least one stress or load member and the volume of the cavities, not

otherwise occupied by the stress or load member or members, being substantially occupied by the metal and plastics mixture (13, 12).

3. A cable as claimed in claim 1 or claim 2 and further characterised in that the sheath or jacket (11) is comprised of a material selected from the group consisting essentially of rubber, polyamides, polyurethane, polyvinyl chloride, polyolefins and mixtures thereof.

4. A cable as claimed in claim 1 or claim 2 and further characterised in that the or each strength member (9, 14) is a stranded wire rope (14) or a link chain (9).

5. A cable as claimed in claim 4 and further characterised in that there are a plurality of stress or load members (9, 14) and these are all link chains (9), or stranded wire ropes (14), or a combination of at least one link chain (9) and one stranded wire rope (14).

6. A cable as claimed in claim 4 or claim 5 and further characterised in that the or each stress of load member (9, 14) is made from materials selected from the group comprising steel, iron, polyamides, aramids and graphite.

7. A cable as claimed in claim 1 or claim 2 and further characterised in that the volume of metal particles (13) occupy 50 to 75 per cent of the sheath volume or the volume of the cavities (17) not otherwise occupied by the stress or load member or members.

8. A cable as claimed in claim 7 and further characterised in that the metal particles (13) are either ferrous or non-ferrous metals or mixtures thereof.

9. A cable as claimed in claim 8 and further characterised in that some of the metal particles (13) are spherical in shape.

10. A cable as claimed in claim 7 and further characterised in that the metal particles (13) are steel and have a particle size of between 0.5 and 1.0 mm.

11. A cable as claimed in claim 7 and further characterised in that the metal particles (13) are of a size such that they will pass a screen having openings of 1 mm.

12. A cable as claimed in claim 1 or claim 2 and further characterised in that the volume of plastics material (12) occupying the sheath volume or the volume of the cavities (17), not otherwise occupied by the stress or load member or members, is between 50 and 25 per cent.

13. A cable as claimed in claim 12 and further characterised in that the plastics material is selected from the group consisting essentially of rubber, polyolefins, polyvinyl chloride, polyamides, polyurethane, and mixtures thereof.

14. An elevator system comprising a car (8) a compensating cable (2) as claimed in any of the preceding claims, a counterweight (4), and a hoist rope (1); the hoist rope being connected to the car and the counterweight and the compensating cable being connected to the counterweight and the car.

### Patentansprüche

1. Ausgleichskabel (2) für insbesondere einen Aufzug, welches ein längliches Gewicht- oder Lasttragglied (9, 14) umfaßt, welches in einem länglichen Mantel (11) angeordnet ist, dadurch gekennzeichnet, daß das Volumen des Mantels (11), welches nicht von dem Gewicht- oder Lasttragglied (9, 14) eingenommen ist, im wesentlichen von einem Gemisch aus Metallteilchen (13) und Kunststoffmaterial (12) besetzt ist.

2. Ausgleichskabel nach Anspruch 1, dadurch gekennzeichnet, daß es flach ist und eine Vielzahl von voneinander beabstandeten Gewicht- oder Lasttraggliedern (9, 14) aufweist, deren jede Längsachse in einer Linie angeordnet und mit den anderen im wesentlichen koplanar verläuft, daß der Mantel eine Hülle (11) aus flexilem Material ist, welches eine Vielzahl länglicher voneinander beabstandeter Hohlräume (17) enthält, daß die Längsachsen der Hohlräume in einer Linie und miteinander im wesentlichen koplanar verlaufen und daß jeder Hohlräum wenigstens ein Gewicht- oder Lasttragglied enthält und das Volumen der Hohlräume, das nicht von den Gewicht- oder Lasttraggliedern eingenommen ist, im wesentlichen von dem Metall-Kunststoffgemisch (13, 12) besetzt ist.

3. Ausgleichskabel nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß der Mantel oder die Hülle (11) aus einem Material, ausgewählt aus der im wesentlichen Gummipolyamide, Polyurethan, Polyvinylchlorid, Polyolefine umfassenden Gruppe und Gemischen hieraus besteht.

4. Ausgleichskabel nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß jedes Zugglied (9, 14) ein geflochtenes Stahlseil (14) oder eine Gelenkkette (9) ist.

5. Ausgleichskabel nach Anspruch 4, dadurch gekennzeichnet, daß eine Vielzahl von Gewicht- oder Lasttraggliedern (9, 14) vorgesehen ist und diese Gelenkketten (9), geflochtene Stahlseile (14) oder eine Kombination wenigstens einer Gelenkkette (9) und eines geflochtenen Stahlseiles (14) sind.

6. Ausgleichskabel nach Anspruch 4 oder 5, dadurch gekennzeichnet, daß das oder jedes Gewicht- oder Lasttragglied (9, 14) aus einem Material hergestellt ist, das aus der Gruppe ausgewählt ist, welche Stahl, Eisen, Polyamide, Aramide und Graphit umfaßt.

7. Ausgleichskabel nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß das Volumen der Metallteilchen (13) 50 bis 75% des Hüllenvolumens oder des Volumens der Hohlräume (17) ausfüllt, das sonst nicht von dem Gewicht- oder Lasttragglied oder -gliedern besetzt ist.

8. Ausgleichskabel nach Anspruch 7, dadurch gekennzeichnet, daß die Metallteilchen (13) entweder eisenhaltige oder nicht-eisenhaltige Metalle oder Gemische hieraus sind.

9. Ausgleichskabel nach Anspruch 8, dadurch gekennzeichnet, daß einige der Metallteilchen (13) eine kugelförmige Form aufweisen.

10. Ausgleichskabel nach Anspruch 7, dadurch

gekennzeichnet, daß die Metallteilchen (13) Stahl sind und eine Teilchengröße von zwischen 0,5 und 1,0 mm aufweisen.

11. Ausgleichskabel nach Anspruch 7, dadurch gekennzeichnet, daß die Metallteilchen (13) eine solche Größe aufweisen, daß sie ein Sieb mit Öffnungen von 1 mm passieren.

12. Ausgleichskabel nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß das Volumen des Kunststoffmaterials (13), welches das Hüllenvolumen oder das Volumen der Hohlräume (17) besetzt, welches sonst nicht von dem Gewicht- oder Lasttragglied oder -gliedern eingenommen ist, zwischen 50 und 25% liegt.

13. Ausgleichskabel nach Anspruch 12, dadurch gekennzeichnet, daß das Kunststoffmaterial aus der Gruppe, im wesentlichen bestehend aus Gummi, Polyolefinen, Polyvinylchlorid, Polyamiden, Polyurethan und Gemischen hieraus ausgewählt ist.

14. Fahrstuhlsystem mit einer Kabine (8) und einem Ausgleichskabel (2) nach einem der vorhergehenden Ansprüche, dadurch gekennzeichnet, daß ein Gegengewicht (4) und ein Flaschenzugseil (1) vorgesehen sind, und daß das Flaschenzugseil (1) mit der Kabine und dem Gegengewicht und das Ausgleichskabel (2) mit dem Gegengewicht und der Kabine verbunden sind.

### Revendications

1. Câble d'équilibrage (2) pour un ascenseur ou l'analogue, comprenant un élément allongé encaissant les efforts ou les charges (9, 14) disposé dans une gaine allongée (11), caractérisé en ce que le volume de la gaine (11) qui n'est pas occupé par l'élément encaissant les efforts ou les charges (9, 14) est pratiquement occupé par un mélange de particules métalliques (13) et de matière plastique (12).

2. Câble selon la revendication 1, caractérisé en ce qu'il est plat et comporte une multiplicité d'éléments espacés encaissant les efforts ou les charges (9, 14), les axes longitudinaux de ces éléments étant alignés partiellement dans le même plan les uns et les autres, en ce que la gaine est une enveloppe (11) de matière flexible contenant une multiplicité de cavités allongées espacées (17), les axes longitudinaux des cavités étant alignés et pratiquement dans le même plan les uns et les autres, et en ce que chaque cavité contient au moins un élément d'efforts ou de charge et que le volume des cavités qui n'est pas par ailleurs occupé par le ou les éléments d'efforts ou de charge, est pratiquement occupé par le mélange de métal et de matière plastique (13, 12).

3. Câble selon la revendication 1 ou la revendication 2, caractérisé en ce que la gaine ou enveloppe (11) est en un matériau choisi dans le groupe comprenant essentiellement le caoutchouc, des polyamides, du polyuréthane, du polychlorure de vinyle, des polyoléfines et leurs mélanges.

4. Câble selon la revendication 1 ou la revendi-

cation 2, caractérisé en ce que le ou chaque élément résistant (9, 14) est un câble de fils métalliques toronnés (14) ou une chaîne à maillons (9).

5. Câble selon la revendication 4, caractérisé en ce qu'il y a une multiplicité d'éléments d'efforts ou de charge (9, 14) et que ce sont tous des chaînes à maillons (9), ou des câbles de fils métalliques toronnés (14), ou une combinaison d'au moins une chaîne à maillons (9) et d'au moins un câble de fils métalliques toronnés (14).

6. Câble selon la revendication 4 ou la revendication 5, caractérisé en ce que le ou chaque élément d'efforts ou de charge (9, 14) est en des matériaux choisis dans le groupe comprenant l'acier, le fer, les polyamides, les aramides et le graphite.

7. Câble selon la revendication 1 ou la revendication 2, caractérisé en ce que les particules métalliques (13) occupent 50 à 75 % du volume de la gaine ou du volume des cavités (17) qui n'est pas par ailleurs occupé par le ou les éléments d'efforts ou de charge.

8. Câble selon la revendication 7, caractérisé en ce que les particules métalliques (13) sont, soit en métal ferreux, soit en métal non ferreux, soit en leurs mélanges.

9. Câble selon la revendication 8, caractérisé en ce que certaines des particules métalliques (13) ont une forme sphérique.

10. Câble selon la revendication 7, caractérisé en ce que les particules métalliques (13) sont en acier et ont une dimension de particules comprise entre 0,5 et 1,00 mm.

5 11. Câble selon la revendication 7, caractérisé en ce que les particules métalliques (13) ont une dimension telle qu'elles passent à travers un tamis ayant des ouvertures de 1 mm.

10 12. Câble selon la revendication 1 ou la revendication 2, caractérisé en ce que la matière plastique (12) occupe le volume de la gaine ou le volume des cavités (17) qui n'est pas par ailleurs occupé par le ou les éléments d'efforts ou de charge, et que ce volume de matière plastique est compris entre 50 à 25%.

15 13. Câble selon la revendication 12, caractérisé en ce que la matière plastique est choisie dans le groupe comprenant essentiellement le caoutchouc, des polyoléfines, du polychlorure de vinyle, des polyamides, du polyuréthane et leurs mélanges.

20 14. Système d'ascenseur comprenant une cabine (8), un câble d'équilibrage (2) selon l'une quelconque des revendications précédentes, un contrepoids (4) et un câble de levage (1), le câble de levage étant raccordé à la cabine et au contrepoids et le câble d'équilibrage étant raccordé ou contrepoids et à la cabine.
